# The Phases of Compilation

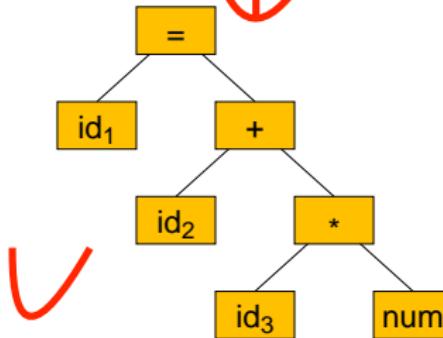

# Syntax Analysis

position = initial + rate \* 60;

id<sub>1</sub> = id<sub>2</sub> + id<sub>3</sub> \* num ;

{id}  
“if”

int if34;

# Outline

## 1 Context-Free Grammars

- Parse Trees
- Leftmost and Rightmost Derivations

## 2 Ambiguity

# Outline

## 1 Context-Free Grammars

- Parse Trees
- Leftmost and Rightmost Derivations

## 2 Ambiguity

# How do we specify language syntax?

- Context-Free Grammars,
- uses special notation (BNF – Backus Naur Form),
- consist of set of rules (productions).

Example:

```
if (x=2) print("yep"); else print("nope");
```

Corresponds to a rule:

$$\text{stm} \rightarrow \text{if } (\text{expr}) \text{ stm else stm}$$

# Context-Free Grammars

Definition (Context-free grammar)

A context-free grammar, or CFG, consists of set terminals, a set of nonterminals, a start symbol, and a set of production.

- The terminals are the tokens.  
- The nonterminals will eventually be “replaced” by terminals (tokens), matching a grammatical pattern.
- The start symbol is a nonterminal.
- For each production,
  - The left side, or head, is a nonterminal.
  - The right side, body, is any string of terminals and nonterminals, including the empty string.

# Example

Example (Context-free grammar)

- Let the terminals be the tokens

$$G = (V, T, S, P)$$

$$V = \{E\}$$

$$T = \{+, *, (,), id\}$$

$$S = E$$

$$\{+, *, (,), id\}.$$

$$E \Rightarrow E + E \Rightarrow id + E \Rightarrow id + id$$

- Let the nonterminals be  $\{E\}$ , which is also the start symbol.
- Let the productions be

- $id * * id$
- $id - id / id$

**Derivations**

**Parse Tree**

$$id ++ id$$

$$E \rightarrow E + E$$

$$E \rightarrow E * E$$

$$E \rightarrow ( E )$$

$$E \rightarrow id$$

$$id + id * id$$

$$(id + id) * id$$

$$(id + id) * (id * id)$$

# Example

Context-free grammars

- We can use the grammar to **derive** strings of terminals if we
  - Begin with the start symbol.
  - Repeatedly replace a nonterminal with the body of a production of which that nonterminal is the head, until the resulting string consists only of terminals.

# Example

Example (Context-free grammar)

- Use the grammar of the example to derive the string

$(\text{id} + \text{id}) * \text{id}.$

# Example

Example (Context-free grammar)

- We typically group together all the productions for a single nonterminal.

$$\underline{E \rightarrow E + E} \mid \underline{E * E} \mid \underline{( E )} \mid \underline{\text{id}}$$

# Outline

## 1 Context-Free Grammars

- Parse Trees
- Leftmost and Rightmost Derivations

## 2 Ambiguity

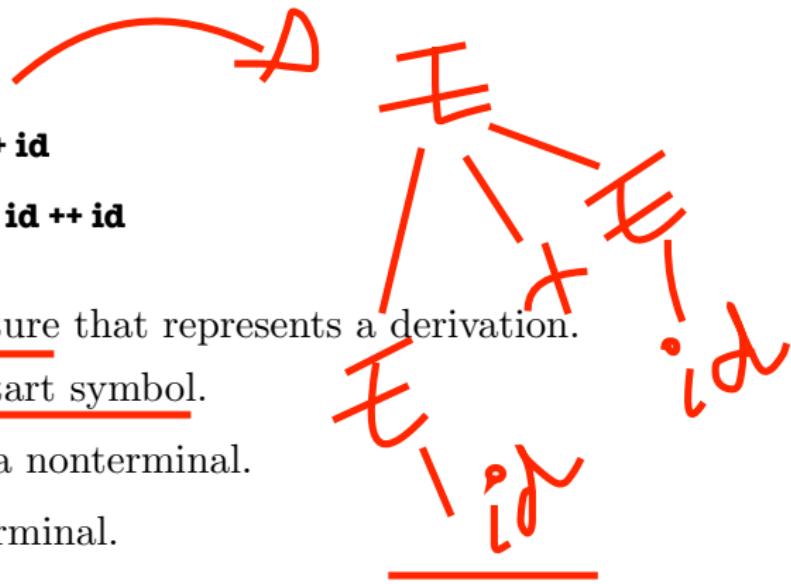

# Parse Trees

$E \Rightarrow E + E \Rightarrow id + E \Rightarrow id + id$   
 $\text{id} ++ id$

Definition (Parse Tree)

A **parse tree** is a tree structure that represents a derivation.

- The root node is the start symbol.
- Every interior node is a nonterminal.
- Every leaf node is a terminal.
- The children of each nonterminal node are the nonterminals and terminals of the body of a production for that nonterminal.

# Example

Example (Parse Tree)

- Draw a parse tree for the derivation of the string

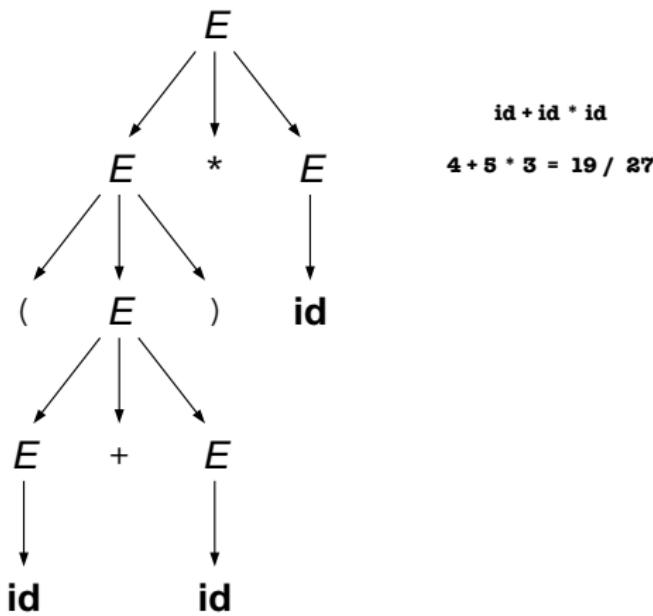

$(\text{id} + \text{id}) * \text{id.}$

# Example

Example (Parse Tree)

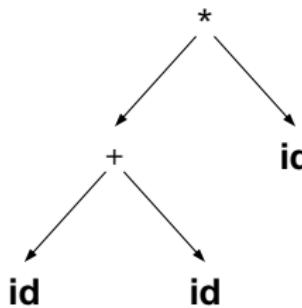

(id + id) \* id

# Example

Example (Parse Tree)

The parse tree is not the same as the syntax tree, which we will study later.

# Outline

## 1 Context-Free Grammars

- Parse Trees
- Leftmost and Rightmost Derivations

## 2 Ambiguity

# Leftmost and Rightmost Derivations

$\text{E} \Rightarrow \text{E} + \text{E} \Rightarrow \text{id} + \text{E} \Rightarrow \text{id} + \text{id}$

$\text{E} \Rightarrow \text{E} + \text{E} \Rightarrow \text{E} + \text{id} \Rightarrow \text{id} + \text{id}$

Definition (Leftmost derivation)

A **leftmost derivation** of a string is a derivation in which, at each step, the leftmost nonterminal is replaced with a string.

Definition (Rightmost derivation)

A **rightmost derivation** of a string is a derivation in which, at each step, the rightmost nonterminal is replaced with a string.

# Example

## Rightmost Derivation

$$\begin{aligned}
 E &\Rightarrow E * E \\
 &\Rightarrow (E) * E \\
 &\Rightarrow (E+E) * E \\
 &\Rightarrow (id + E) * E \\
 &\Rightarrow (id + id) * E \\
 &\Rightarrow (id + id) * id
 \end{aligned}$$

$$\begin{aligned}
 E &\Rightarrow E * E \\
 &\Rightarrow E * id \\
 &\Rightarrow (E) * id \\
 &\Rightarrow (E+E) * id \\
 &\cancel{\Rightarrow (E + id) * id} \\
 \textcolor{red}{\cancel{E}} &\Rightarrow (id + id) * id
 \end{aligned}$$

Example (Leftmost and rightmost derivations)

Using the grammar

$$E \rightarrow E + E | E * E | ( E ) | id$$

find leftmost and rightmost derivations of **(id+id)\*id.**

id \*\* id

**E**  $\Rightarrow$  **E** \* **E**

# Outline

## 1 Context-Free Grammars

- Parse Trees
- Leftmost and Rightmost Derivations

## 2 Ambiguity

# Ambiguity

- Some grammars provide more than one way to derive a string.
- For example, **id+id\*id** can be derived in two different ways using the grammar rules

$$E \rightarrow E + E \mid E * E \mid ( E ) \mid \text{id}$$

# Ambiguity

Definition (Ambiguous grammar)

A grammar is **ambiguous** if its language contains a string that has more than one leftmost derivation under that grammar.

Definition (Inherently ambiguous language)

A language is **inherently ambiguous** if every grammar for that language is ambiguous.

# Example

Example (Unambiguous Grammar)

The same language can be derived unambiguously from the following grammar.

$$E \rightarrow E + T \mid T$$

$$T \rightarrow T * F \mid F$$

$$F \rightarrow ( E ) \mid \text{id}$$

# Example

Example (Unambiguous Grammar)

Using the grammar

$$E \rightarrow E + T \mid T$$

$$T \rightarrow T * F \mid F$$

$$F \rightarrow ( E ) \mid \text{id}$$

- Find a leftmost derivation of **id+id\*id.**
- Find a leftmost derivation of **id\*id+id.**
- Draw the parse trees.
